**ABSTRACT**

Feline Panleukopenia (FP) is a highly infectious disease in the felidae family and has not been found in human. FP is caused by feline panleukopenia virus (FPV) from the parvoviridae family. FPV has a very high mortality and morbidity rates. Symptoms from this disease is a high fever, appetite loss, vomit which occur from the high fever, and hypersalivation. Most cases for FPV is happen on stray cat. The growing population of the stray cat can increase the risk of the FPV. The aim for this study is to find the potential of the feline panleukopenia virus spread on the stray cat from east Surabaya using the FPV rapid test kit ag and the sample from the cat anus. The results showed that there was one adult male cat with an incidence percentage of 0.03% which detected the presence of FPV antigen.

**Keywords:** Feline panleukopenia Virus (FPV); stray cats; rapid test kit FPV Ag

**INTRODUCTION**

Feline panleukopenia (FP) is a highly contagious infectious disease in the felidae family and has not been found in human. FP is caused by Feline panleukopenia virus (FPV) of the parvoviridae family. FPV have a very high mortality and morbidity rate5. Symptoms that FPV can cause is high fever, decreased appetite, vomiting usually occurs after high fever and sometimes hypersalivation5. FPV also has subclinical symptoms that means the cat does not show a certain symptom or a mild form of medical condition5. This subclinical case, occurs a lot in adult cats6. This can happen because the cat has been infected with FPV and then recovered or have been vaccinated, which makes the cat stronger against attacks from FPV. However, this does not rule out the possibility of a cat with Subclinical symptoms to transmit this disease to other cats6. On subclinical stage, prevention efforts are needed so that there is no secondary infection that makes the cat infected with FPV condition worse7.

FPV cases are more frequent in stray cats, Islam et al10 said that the prevalence of FPV in stray cats (41.67%) is higher compared to a house cat (17.39%). This can happen because stray cats did not get animal welfare, such as a place to live7, 10 deworming vitamin, food and a vaccine. In addition, stray cats have wider roaming range compared to a pet cat according to Meek11 stray cats roaming area is up to 5.1 Ha while house cat only 2.9 Ha, this wider roaming territory can also be one of the factors that causes more stray cats is at risk of developing FPV.

Population of stray cat keep increasing because cat is an animal that is seasonally polyestrus12 it means cat have seasonal estrous and are able to conceive several times a year with each birth has approximately 3 kittens. The increase of stray cat population will pose more risk to FPV.
RESULTS AND DISCUSSION

</table>

In the descriptive table above, it can be seen that there are 30 stray cat’s anal swab samples and showed 29 negative samples and there was one positive number from the Semolowaru, Sukolilo District. From these results, it appears that two lines are formed on the C line and the T line.

From the results of these data, it can be seen the percentage of parvovirus events that causes Feline panleukopenia on stray cats in the East Surabaya Region is 0.03%. This percentage was based on the formula:

Event percentage = (Σ positive samples) / (Σ all samples) × 100%  
= 1/30 × 100%  
= 0.03%

RESULTS AND DISCUSSION

The results of the research on the incidence of parvovirus that causes FP in stray cats seem to show positive results in adult male cats. In the research of Bukar-kolo et al.14 the prevalence of FPV positive male cats 7% and 6.5% female cat. FPV incidence in male cats is higher probably due to the wider roaming area than the female cat which makes the males are more at risk of getting infected with FPV. According to Hansen15 male cats has a 2 times wider home range than female cats. Beside the gender, there is the location factor. The market is damp and also dirty which is the source of disease infection with no exception of FPV in stray cats that lives on the market.

In the research results, there are 2 lines on the Rapid Test Kit FPV ag with a line at the C mark, which means Control and T which means Test. This shows there are positive results but the T line looks faint and not as clear as on line C. The adult male cat showed clinical symptoms that leads the cat to be infected with FPV. The cat has a fever but no diarrhea which according to Squires23 diarrhea occurs after one to two days of FPV infection, it is possible that the antibody titer to FPV is still low or under cut off17 which causes faint lines to form. Detection limit of the Rapid Test Kit FPV ag is approximately 104(TQD)19/0.1 ml18.

The percentage of results shows 0.03% which is a very small number. The possibility of this happening is because of the climate when the study was conducted. Halid19 said that FPV infection is higher during the rainy season. According to BMKG20 in March on East Surabaya is the end of the rainy season and categorized as normal. Another possibility is the low survival rate because FPV is a disease with high mortality rate to 100%.21. Untreated adult cat mortality rate reaches 85% and mortality in untreated kitten reaches 100%.22. FPV-infected cats are most likely died before sampled.

The results of this study are different with research conducted by Mahendra23. Compared to the previous research, which the data was collected from medical records at the veterinary clinic and a veterinary hospital. It is possible that cats infected with FPV are housecats which their health, environmental conditions and temperature are always monitored. This research method is only done at one time and using stray cats that the health, condition and temperature is unknown. So, when doing this research, it is very difficult to find a stray cat that is infected with FPV, with high mortality and without treatment and therapy.

The main prevention that can be done is vaccination of cats, even if the vaccination cannot completely guarantee the cat won’t be infected but at least the cat will be stronger against FPV infection24. The first vaccination can be done from the age of 8-9 weeks.25

CONCLUSION

Based on research results regarding the incidence of parvovirus in stray cats in some market at East Surabaya using Rapid Test Kit FPV ag in March to April 2022, it can be concluded that there is one adult male cat with percentage 0.03% incidence detected FP virus.
